E-machine Optimization considering Electric Drive Unit (EDU) System Requirements

Dr. Jonathan Godbehere – Motor Design Ltd

17th June 2021

- Company Introduction
- Electric Drive Unit (EDU) design: trends and challenges
- IPM traction motor optimization within an EDU system
- Next steps in the design process
- Summary

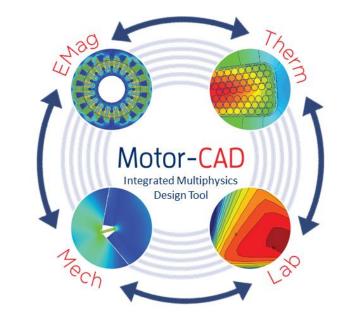

Ansys Motor-CAD & Motor Design Ltd

Software developers: ANSYS Motor-CAD

- Design, analysis and optimization of electric motors
- High level of customer support & engineering know-how
- Embedded engineering expertise

Consultancy

- Design, analysis and training courses
- Led by motor design experts
- Research
 - Government / EU-funded research projects
 - Collaborate with universities worldwide

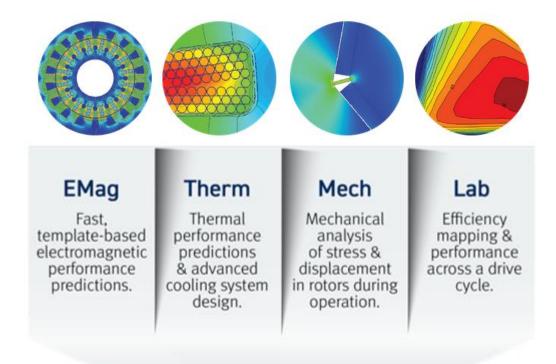

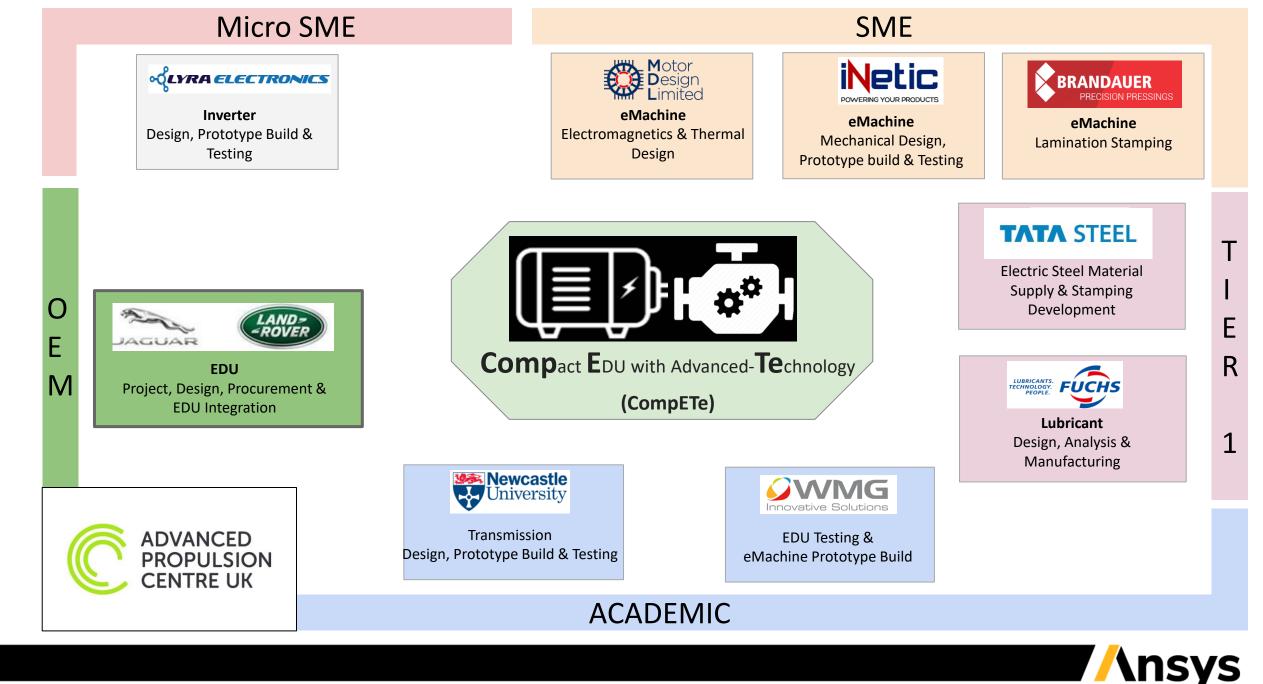

Ansys Motor-CAD software Integrated multiphysics design tool

- Ansys Motor-CAD is the market leading tool dedicated to the design and analysis of electric motors.
- Combines analytical and FE methods for fast and accurate performance prediction.
- Enables rapid and accurate Multiphysics design of electric machines across the full operating envelope.

Quickly and iteratively evaluate motor topologies and concepts to produce designs that are optimized for size, performance and efficiency.

LEADING ELECTRIFICATION

ELECTRIFIED PORTFOLIO

Electrification across our product range continues with 1 Battery Electric Vehicle (BEV), 8 models now on sale with plug-in hybrids (PHEV) and 11 with mild-hybrids (MHEV).

WORLD CAR OF THE YEAR

Jaguar I-PACE won an **unprecedented treble**; 2019 World Car of the Year, World Design Car of the Year and World Green Car of the Year, alongside over 80 global industry awards.

ELECTRIFIED SALES

Achieved **6% electrified sales** in 2019, with a commitment to offer electrified options for all new models from 2020

Company Introduction

• Electric Drive Unit (EDU) design: trends and challenges

- IPM traction motor optimization within and EDU system
- Next steps in the design process
- Summary

Electric Drive Unit (EDU) design: trends and challenges Need for multi-criteria design process

Higher efficiency

Increased torque and power density

\$ Reduced costs

Increasing volumes and mass production

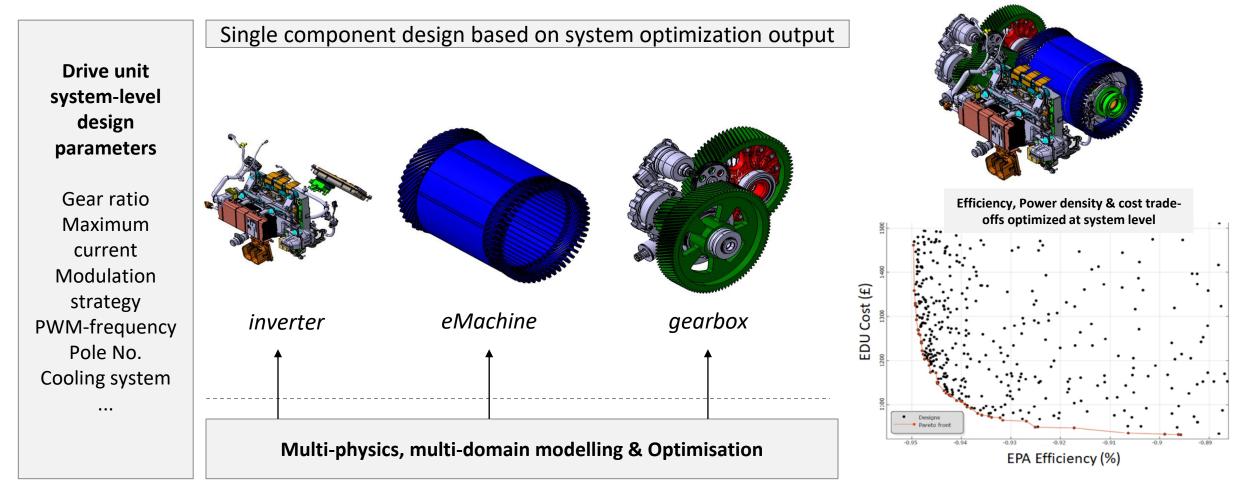

- Increased integration
- Shorter development cycles

Need for Multi-Physics Analysis and Optimization to meet EDU targets

Effective multi-physics analysis allows true optimization targeting the integrated drive unit (system) requirements.

Electric Drive Unit (EDU) design: trends and challenges Need for a system led design process

Particular example of the eMachine

Inverter and gearbox selection add an additional system-level loop to the optimisation run with max. current, speed and dimensions of the eMachine boundaries becoming variable input parameters

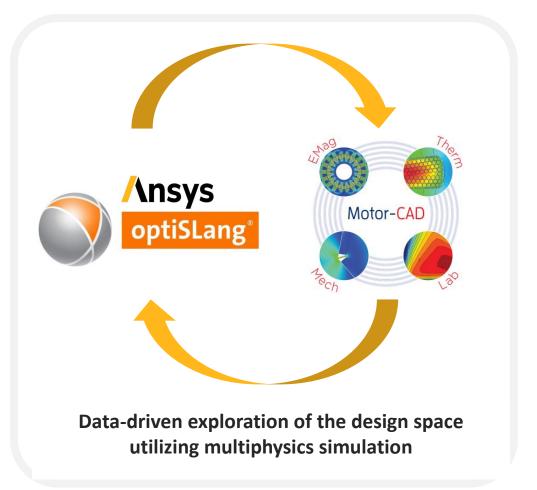

Problem Statement

- In EDU development we are aiming for the highest drive cycle efficiency, lowest cost and smallest volume for a given performance
- To achieve this we need to make design decisions with regards to motor, inverter and gearbox that consider the whole EDU performance
- The optimal individual components ≠ optimal overall system
- Can the E-machine be optimized in such a way, where these interactions are accounted for?

Yes! By combining forces between **Motor-CAD** and **optiSlang** we can create a new and unique system optimization solution

- Company Introduction
- Electric Drive Unit (EDU) design: trends and challenges
- IPM traction motor optimization within an EDU system
- Next steps in the design process
- Summary

EDU Specifications

• EDU output:

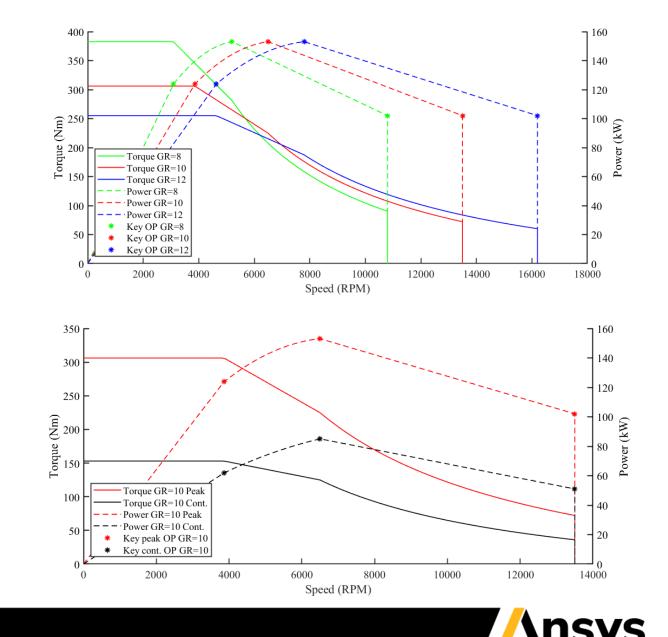

- Max. speed = 100 MPH
- Max. axle torque = 3000 Nm
- Max. EDU power = 150 kW
- Peak power @ peak torque ≈ 120 kW
- Peak power @ max. speed = 100 kW

• Transmission:

- 2-stage, single speed transmission
- Gear ratio 8 12

• Inverter:

- SiC technology: 720 V_{dc}
- Maximum current = $200 300 A_{rms}$
- E-machine requirements:
 - Maximum stator outer diameter = 210 mm
 - Maximum active length = 165 mm
 - Continuous (thermal steady-state) power requirements, alongside the peak

IPM traction motor optimization scenario

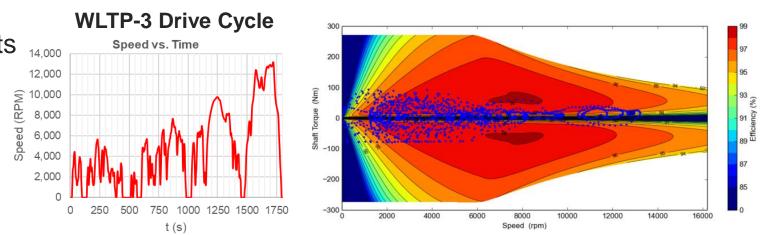

Multi-objective:

- Min energy consumption over WLTP-3
- Min active mass
- Min material cost
- Multi-constraints:
 - Peak Power @ 3 operating points:
 - Peak torque, peak power & max. speed
 - Continuous Power @ 3 operating points
 - Peak torque, peak power & max. speed
 - Rotor stress @ 20% overspeed
 - Average and maximum values

- V-IPM motor
- 48 slots, 8 poles
- Hairpin winding
- Water jacket cooling

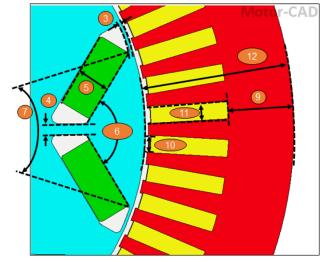

Design Space including EDU parameters

	Parameter	lb	ub	Unit
1	Active length	95	165	mm
2	Gear ratio	8	12	
3	Bridge thickness	0.7	2.0	mm
4	Magnet post thickness	1.5	4.0	mm
5	Magnet thickness	2.5	6.0	mm
6	V pole angle	90	160	ο
7	Pole arc ratio*	0.4	0.8	
8	Web thickness ratio*	0.05	0.5	
9	Slot depth ratio*	0.40	0.65	
10	Slot opening ratio*	0.30	0.85	
11	Slot width ratio*	0.45	0.67	
12	Stator bore ratio*	0.66	0.77	
13	Max. inverter current	200	300	A _{rms}
14	Stator outer diameter	160	210	mm

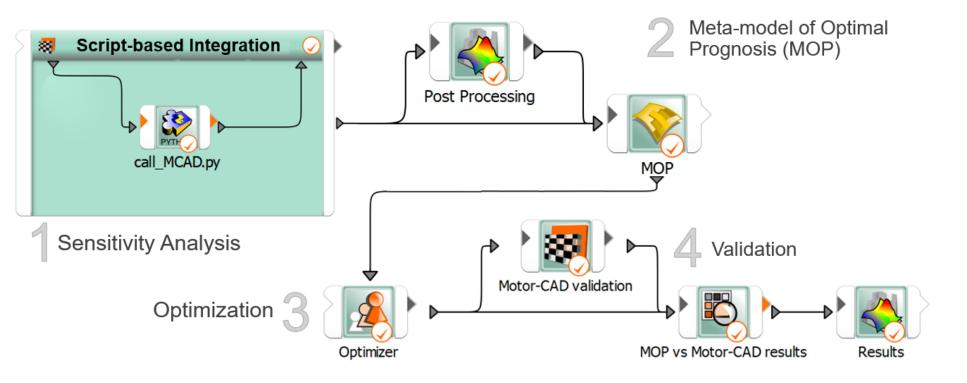

* Ansys Motor-CAD v14 - V-IPM (web) template

- Ratio based parameterization (V14) enables easy scaling over a broad design space
- Full motor parametric study is undertaken: 600 cases, 15-20 min per case so a total of ~2 days (parallelisation possible to reduce simulation time)
- Key EDU design parameters are added inputs to the design space:
 - Traction motor space envelope
 - Gear Ratio
 - Inverter Current

Optimization Workflow

A Meta-model of Optimal Prognosis (MOP) of the Emachine is built through a sensitivity analysis, using Motor-CAD.

The MOP model is then used in optimization stage to create pareto fronts of 'best designs'

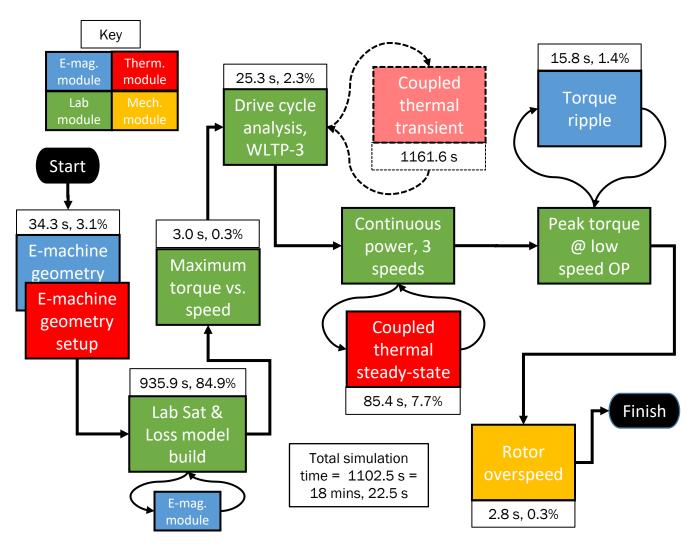

'Best designs' are validated in Motor-CAD

Motor-CAD V-IPM Script Simulation Workflow

• A multi-physics simulation strategy is utilised:

- Coupled Electromagnetic-thermal simulations
- Mechanical stress
- Max. current is an input:
 - Max. current is used to assess peak torque & power
 - Sets a limit when max. current not required
- Gear ratio as an input:
 - Scales speed within the Motor-CAD simulation
 - Dictates the maximum working speed and over-speed of the E-machine
 - Output power is sampled at key operating points: 3 for peak and 3 for continuous
- WLTP class-3 automotive drive cycle generated using vehicle model.
 - Gear ratio changes the E-machine torque and speed in the automotive drive cycles
 - 1800 data points, sampled at 1 second intervals

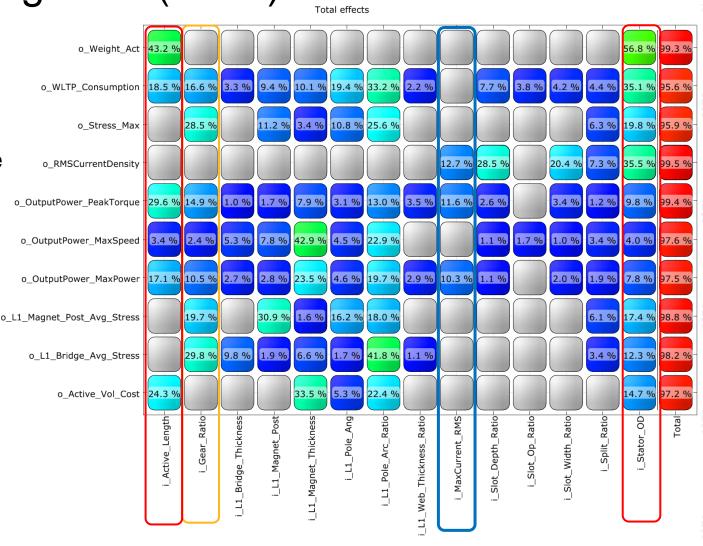

Meta-model of Optimal Prognosis (MOP)

Model

- Matrix that shows the Coefficient of Prognosis (CoP) of all output parameters with respect to input parameters:
 - Input parameters to the sensitivity analysis are shown horizontally
 - Output parameters, i.e. constraints and objectives are shown vertically
 - Last column shows overall quality of the Metamodel – good quality achieved
- EDU system input parameters: space envelope, gear ratio and inverter current all have measurable impacts on numerous constraints and objectives

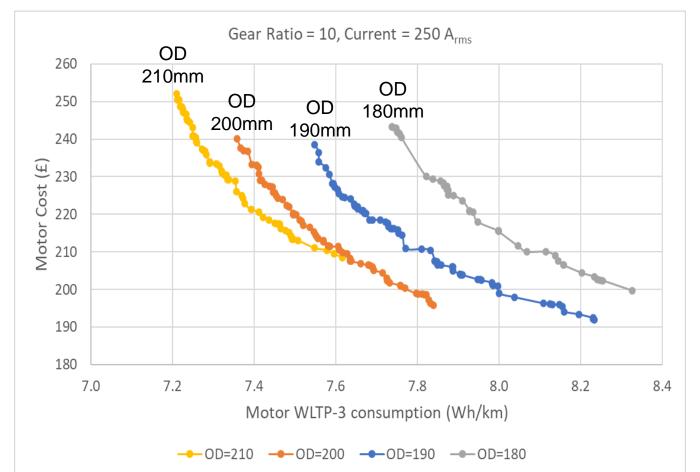

Parameter

Optimization Results: Motor Packaging vs Performance

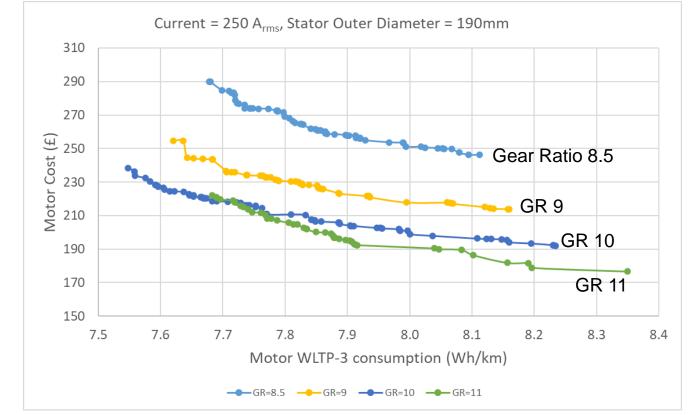

- The motor space envelope is often constraint within the overall EDU packaging
- Pareto fronts show impact of increasing motor volume on motor cost and energy consumption
 - Increasing stator Outer Diameter (OD) with constant motor length increases the motor space envelope
 - A higher motor space envelope reduces motor energy consumption
- Compromise between motor volume, cost and energy efficiency can easily be quantified

Trade-off between motor volume and competing component packaging requirements can be communicated to system engineering team

Optimization results: Impact of gear ratio on motor performance

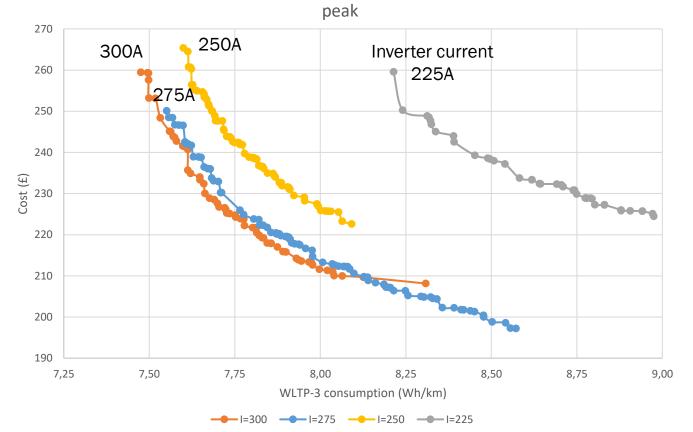

- The transmission gear ratio determines the maximum motor speed and peak torque
- Pareto fronts show impact of increasing gear ratio on motor cost and energy consumption
 - A higher gear ratio/motor speed reduces motor cost and energy consumption
 - Also increases motor bearing loss
- A higher gear ratio often increases transmission cost

Using the graphs shown design trade-offs between motor and transmission can easily be quantified and communicated between different component teams

Optimiszation results: Impact of inverter current on motor performance Gear Ratio = 10, Stator Outer Diameter = 190 mm, Cont. power = 70%

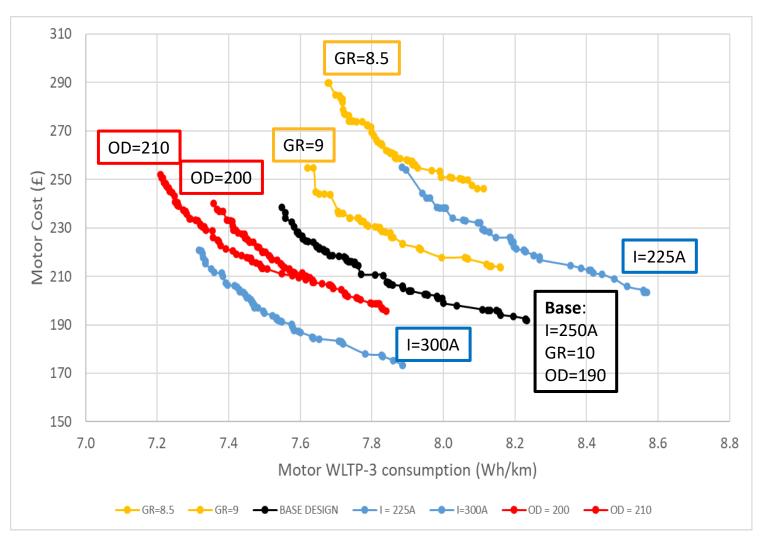

- The maximum inverter current determines the peak torque and power the motor can deliver
- Pareto front shows the impact of increasing the inverter current on motor cost and energy consumption
 - A higher inverter current reduces motor cost and increases motor efficiency
 - A motor thermal limit is eventually encountered, when increasing the inverter current
- A higher inverter current does increase inverter VA rating and inverter loss

Using the graphs shown design trade-offs between motor and inverter can easily be quantified and communicated between different component teams

System EDU Optimization Results and Design Trade-offs

- Motor energy consumption and cost varying with motor OD, inverter current and gear ratio
- Extremely powerful tool to quantify system design trade-offs
- Results enable ease of communication between motor designer, system engineers and component designers
- Easily presentable enabling management to make quantifiable system design trade-offs:
 - % reduction in motor energy consumption requires % increase in space/current/gear ratio
- Optimization of 18,000+ cases based on Meta Model approach took ~30 min, compared to ~80 days if done manually

- Company Introduction
- Electric Drive Unit (EDU) design: trends and challenges
- IPM traction motor optimization within an EDU system
- Next steps in the design process
- Summary

Next steps: repeat with different E-machine topologies

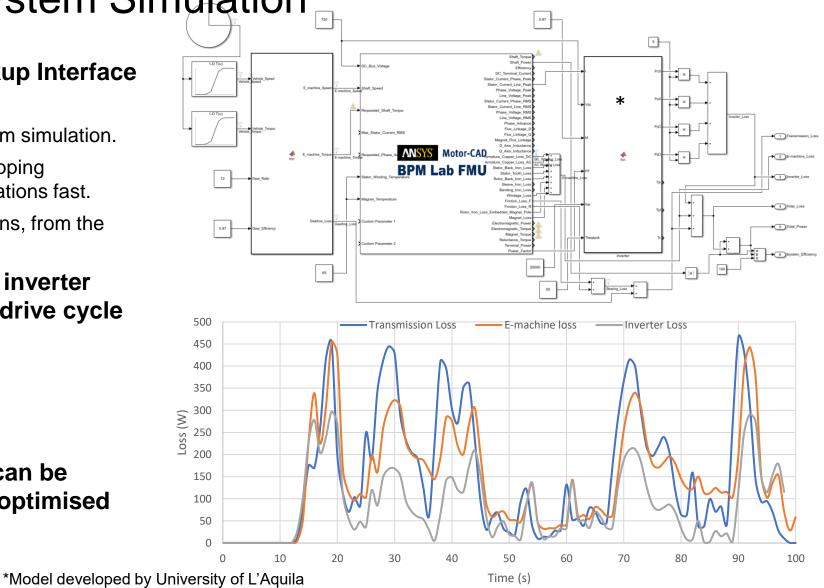

- Meta-model simulation time:
 - \approx 20 mins per iteration
 - 400 to 600 samples
 - 8 Motor-CAD black-box in parallel
 - ≈ 16.7 to 25 hours
- One meta-model gives an extremely wide design space to explore.
- Meta-model simulation time is short enough that more motor topologies can easily be investigated, for example:
 - Different pole and slot numbers
 - Different winding topologies
 - Different rotor topologies
 - Different active materials

Next steps: EDU System Simulation

- Ansys Motor-CAD Function Mockup Interface (FMI):
 - Runs Motor-CAD files live within a system simulation.
 - The Lab module saturation and loss mapping techniques, keep electromagnetic simulations fast.
 - Easily load in different Motor-CAD designs, from the previous optimisation procedure
- Combined with transmission and inverter models, we compute the WLTP-3 drive cycle consumption per component:
 - Transmission = 7.14 Wh/km
 - E-machine = 6.90 Wh/km
 - Inverter = 4.30 Wh/km
- The various EDU configurations can be benchmarked in full, allowing an optimised system solution.

- System design and optimisation drives faster, lower cost development processes as well as better overall performance of the Electric Drive Unit system.
- A combined optimization workflow with Ansys Motor-CAD and Ansys OptiSLang provides a unique, unparalleled solution for full design exploration of E-machines including EDU system influences.
- The workflow presented provides insight in key design trade-offs between e-machine, inverter and transmission performance against system design objectives, such as mass, cost and energy consumption.
- These results enable ease of communication between the component designers for the e-machine, inverter and transmission, as well as the system design teams responsible for the key attributes and requirement cascading.
